54 **Track for blinds.**

57 A blind apparatus comprising at least two tracks having adjacent ends meeting at a corner defined there between, the tracks defining two opposite ends remote from such corner, a rotation shaft for each track, a lead traveller in each track, moving along a lead traveller path of predetermined length from an open position at one end of the path to a closed position at the other end of the path, pluralities of travellers, forming groups, associated with respective lead travellers, each traveller having a rotatable slat shaft and being connected to a rotation shaft whereby upon rotation of the rotation shaft, the slat shaft may be rotated, adjacent travellers in the same group being connected by links, each lead traveller being connected to an adjacent traveller in its respective group by a further link, a flexible control element attachable to the lead travellers, and, a flexible coupling connecting adjacent rotation shafts at the corner, with all lead travellers being movable simultaneously along respective paths by the flexible control element.

DESCRIPTIONTRACK FOR BLINDS

The invention relates to an apparatus for operating blinds, and in particular, the invention relates to an apparatus for operating vertical blinds around a corner.

Vertical blinds generally comprise a plurality of evenly spaced vertical slats, downwardly depending from travellers held in a horizontal track. The track is affixed to the ceiling or upper casement of a window. Each slat is rotatably attached to a single traveller which is slidable within the track. Commonly, a horizontal shaft connects all the travellers. Rotation of the shaft, through a suitable means in each traveller (such as a worm gear) causes the slats to rotate. Each traveller is connected to adjacent travellers by suitable movable connection means whereby, in one direction each traveller can be moved to contact another traveller, and, in an opposite direction the travellers move apart from each other. Suitable control means (such as cords, chains, or shafts) are provided whereby the travellers can be moved longitudinally along the track, and whereby the shaft can be turned to rotate the vertical slats. Generally, such controls are located at one end of the track.

In existing vertical blinds the track is straight.
In order to have vertical blinds on both sides of a corner,
for instance in a bay window or in a room having glass sides
joining at corners, it is necessary to have a separate
5 vertical blind arrangement along each window. Each blind
must be operated individually, independently of the other
blinds. Each blind requires its own control cords or shafts.
These requirements add inconvenience and added expense to
the vertical blind system. As well, the additional control
10 cords or shafts detract from the aesthetic appearance of
the window.

Where the two linear blind tracks meet, in the
corner, there is a gap where the slats do not meet.

Where the lengths of track contain groups of travellers
15 of different numbers, the travellers in all groups should
be capable of being moved between fully open and fully
closed positions simultaneously, by a single control.

It would therefore be advantageous to provide a
vertical blind which could extend around corners and which
20 would require only a single control cord or shaft.
Furthermore, it would be also advantageous if such a blind
could be devised to operate around a multiplicity of corners
along different lengths of window. Furthermore, in certain
applications it would also be advantageous if the blind
25 apparatus could be oriented in any position including
vertically, horizontally or in any other position.

With a view to overcoming the above disadvantages and
to providing the above advantages, the invention comprises
a blind apparatus comprising at least two tracks having
30 adjacent ends meeting at a corner defined therebetween,
the tracks defining two opposite ends remote from such
corner, a rotation shaft longitudinally located relative to

each track, at least one lead traveller slidably received within each track, each lead traveller being movable along a lead traveller path of predetermined length from an open position at one end of the path to a closed position at the other end of the path; a plurality of travellers, forming a group, associated with each lead traveller, the travellers being slidably received within a track, each traveller having a rotatable slat shaft, each traveller being connected by suitable transmission means to one of the rotation shafts whereby upon rotation of the rotation shaft, the slat shaft may be rotated, adjacent travellers in the same group being connected by longitudinal control means attachable to the lead travellers, a rotation control attached to a rotation shaft, and, flexible coupling means connecting adjacent rotation shafts at the corner.

The invention achieves the above advantages by providing a rotation shaft within the track. Each shaft is connected to an adjacent shaft around a corner by a suitable universal flexible coupling means, whereby rotation of one shaft will induce rotation in the other shaft. Furthermore, the lead traveller with the longest lead traveller path is connected to a control cord. The control cord is also connected by a movable connection to the other lead travellers.

The connection means connecting the cord to respective lead travellers is such that all travellers in all groups will reach the fully opened or the fully closed position at the same time.

In one form, connectors are located at spaced points on the cord. In another form the connectors can be frictional sliding devices like a clutch providing a sliding grip.

DETAILED DESCRIPTION OF A SPECIFIC EMBODIMENT

Referring to Figure 1, there is illustrated a bay window indicated generally as 10. Bay window 10 comprises, in this illustration, left side 12, front side 14, and right side 16. Left side 12 is joined to front side 14 at corner 18. Similarly, front side 14 and right side 16 are joined at another corner 20. The sides 12, 14 and 16 may each define different lengths. As well, corners 18 and 20 may define different angles. The left side 12 of window 10 includes an upper casement 22. Similarly, sides

20

25

14 and 16 include upper casements 24 and 26 respectively. A vertical blind apparatus, according to the invention, indicated generally as 28, is affixed to and depends downwardly from upper casements 22, 24 and 26.

5 The invention is equally applicable to two sides, or four, or more.

Vertical blind apparatus 28 comprises horizontal tracks 30, 32 and 34 affixed respectively to upper casements 22, 24 and 26 and mitered together at corners 18 and 20. Slidably held within tracks 30, 32 and 34 are a plurality of travellers 36 (see Figure 2). Rotatably attached to each traveller 36 is a downwardly depending slat 38. Slat 38 generally comprises an opaque material, so that when the vertical blind apparatus 28 is in a closed position light is prevented from entering bay window 10.

Travellers 36 slidably support slats 38. Furthermore, travellers 36 are interconnected by suitable movable link means 82, as discussed below, for longitudinally moving the travellers 36.

0 For convenient operation, free ends 54a and 56a of longitudinal control cords 54 and 56 depend from a free end of track 34, at one end of the blind. A suitable pulley (not shown) may be provided at such end to allow for smooth movement of cords 54 and 56. Cords 54 and 56 are connected, as disclosed herein, to a lead traveller (as, for example, lead traveller 36a or 36b in Figure 3) in each track 30, 32 and 34. At an opposite end of vertical blind apparatus 28, cords 54 and 56 are joined together and, in fact, may be integral with each other. A suitable pulley (not shown) may be provided at such opposite end to allow for smooth movement of cords 54 and 56. The free

ends 54a and 56a of cords 54 and 56, respectively, may be tied or otherwise connected together and, in fact, may be integral with each other.

5 Cords 54 and 56 may be pulled to move travellers 36 longitudinally within tracks 30, 32 and 34. Such longitudinal movement causes slats 38 to be drawn sideways between open and closed positions, as well as through intermediate positions therebetween.

10 In order to rotate slats 38, travellers 36 are each connected to a rotation shaft 40 (see Figure 2), as described below. In order to rotate shaft 40 a suitable rotation control means, such as cord 41, is provided. Cord 41 depends from shaft 40, preferably at the same end of track 34 as free ends 54a and 56a of cords 54 and 56.
15 Suitable means (such as a pulley 43) is provided whereby movement of cord 41 will rotate shaft 40. It will be appreciated that other control means, such as chains, shafts or the like, may be used.

20 Rotation transmission means, typically worm gears (not shown), are incorporated in each traveller 36, and connected between the rotation shaft 40 and respective slats 38. Rotation of such worm gear rotates the slats 38.

25 Lead travellers 36a and 36b are movable along lead traveller paths 35 and 33, respectively (indicated in phantom in Figure 3). Paths 35 and 33 have predetermined path lengths. In the illustrated embodiment, such path lengths correspond generally to the length of the tracks 32 and 34 (with an allowance for the length of the
30 collapsed travellers 36 in the open position). However, the path lengths could be restricted to any fraction of

the lengths of the tracks 32 and 34. Such restriction may be necessary, for example, in the situation where more than one lead traveller is provided in the same track (as in the case of a centre pull opening or multiple opening vertical blind apparatus).

Generally, the length of the path will depend upon the number of travellers in the track. The number of travellers will in turn depend on the width of the window (or space) to be covered by the slats.

The invention permits the movement of travellers arranged in groups of travellers of unequal numbers, in a manner to be described below.

It is not intended to restrict the scope of the invention to the particular window arrangement or track arrangement illustrated. Rather it is the intention that the scope of the invention cover any application of a vertical blind apparatus defining regular or rounded corners. Similarly, it is not intended to restrict the scope of the invention to the particular track and traveller assemblies disclosed. Rather, it is the intention that the scope of the invention include any track design and traveller design.

Referring to Figure 2, there are illustrated tracks 32 and 34 meeting at a corner, indicated generally as 20. Tracks 32 and 34 are affixed by any suitable means to upper casements 24 and 26, respectively (see Figure 1). Travellers 36 are slidably held within tracks 32 and 34. Each traveller 36 includes a rotatable slat shaft 37. A slat 38 is affixed to each slat shaft 37.

A rotation shaft 40 extends along the length of each

track 32 and 34 from one end to the other. Shaft 40 is rotatably supported by a suitable support means, such as bearing blocks 42 affixed at each end of tracks 32 and 34. Bearing block 42 defines a suitable hole allowing shaft 40 to extend therethrough. Similarly, each traveller 5 36 defines a suitable opening allowing shaft 40 to pass therethrough. A suitable gear or other transmission means known in the art (not shown) is included in each traveller 36 and is adapted to cooperate with shaft 40, whereby 10 rotation of shaft 40 will induce each slat shaft 37 to rotate. Rotation of slat shafts 37 in unison will cause slats 38 to either open or close, as desired. In order to rotate shaft 40, a suitable pulley 43, or other means, may be attached at one end of shaft 40 and may be operable 15 by a suitable cord, chain or other means (see cord 41 in Figure 1).

Adjacent shafts 40 are connected together at corner 20 by flexible coupling means 44. The bearing blocks 42 are arranged at either end of the flexible coupling means 44 to locate the ends of the shafts 40 adjacent the flexible coupling means 44. In the illustrated embodiment, flexible coupling means 44 comprises a cylindrical helical spring 46 affixed to collars 48 at each end. Collars 48 in turn are affixed by suitable means, such as set screw 50, to 25 each shaft 40. For protection and for ease of rotation, washers 52 may be inserted in place between collars 48 and bearing blocks 42. Each collar 48 defines a boss 48a extending therefrom in order to assist in affixing spring 46 to collars 48. The spring 46 may be wrapped around and 30 affixed to the bosses 48a by suitable means.

Other flexible coupling means may be used. For example, a spring, a universal joint, or a series of universal joints, a flexible hose (such as a rubber hose)

or a flexible cable (such as is used in a speedometer cable) may be used.

As described below, cords 54 and 56 are used to move travellers 36 longitudinally within tracks 32 and 34 in order to open and close the vertical blind apparatus 28. In order to allow cords 54 and 56 to pass without restriction around corner 20, a dual pulley arrangement 58 is affixed between tracks 34 and 32 at corner 20. Dual pulley 58 includes two pulley wheels 58a, rotatable in opposite directions. Cord 54 lies within the groove of one such pulley wheel 58a and cord 56 lies within the groove of the other pulley wheel 58a.

In other embodiments it may not be necessary to use a dual pulley 58. For instance, a smooth rounded plate, effectively rounding off corner 20 or a bent hollow tube may be found suitable. However, it has been found that upon occasion such plates or tubes may cause cords 54 and 56 to bind together, thereby interfering with the smooth functioning of the vertical blind apparatus. It has been found that the dual pulley arrangement is preferable.

Referring to Figure 3, a schematic plan view of tracks 32 and 34 meeting at corner 20 is provided. The outline of tracks 32 and 34 is shown in phantom. Groups of travellers 36 are constrained to move within tracks 32 and 34. As illustrated here, track 34 has a group of five travellers, and track 32 has a group of four travellers. As a result lead traveller path 35 in track 34 is somewhat longer than lead traveller path 33 in track 32.

In order to allow the vertical blind apparatus 28 to open and close evenly, even though paths 33 and 35 are of different lengths, cords 54 and 56 are provided with movable connectors for connection to the lead travellers.

Cords 54 and 56 are integral with each other, or tied together, at one end. At the other end the free ends 54a and 56a of cords 54 and 56 depend downwardly. A human operator may open and close the blinds by pulling on the free ends 54a and 56a of cords 54 and 56. Cord 56 is connected to the lead traveller 36a in track 34, having the longest path, in this case path 35. Cord 54 is connected, as described below, to the lead traveller 36b in path 33, the shorter path.

Referring to Figure 4, lead traveller 36a is illustrated. One means of attaching cord 56 to traveller 36a is to attach traveller engagement means 64 to cord 56 between two panels 66 and 68 of traveller 36a. Panels 66 and 68 define suitable openings allowing cord 56 to pass therethrough. When cord 56 is pulled in one direction or the other, engagement means 64 will engage and abut against either panel 66 or panel 68, thereby causing lead traveller 36a to move. Engagement means 64 may comprise a spherical ball which is crimped about cord 56. Other means of attaching cord 56 to traveller 36a may be used. For example, cord 56 may simply be tied to or wrapped around a portion of traveller 36a.

Referring to Figure 5, lead traveller 36b is shown. Traveller 36b may include panels 70 and 72, each panel 70 and 72 defining an opening 74 therein. Cord 54 passes through openings 74. Between panels 70 and 72 a washer 76 may be loosely arranged around cord 54. The outer diameter of washer 76 is sufficiently large that washer 76 cannot pass through openings 74. The blind in the fully open position, with cord 54 being pulled taut and about to commence closing vertical blind apparatus 28. A first traveller engagement means 80 is affixed to cord 54 adjacent panel 72. Similarly, a second engagement means 78

78 is affixed to cord 56, but is spaced apart from engagement means 80 by an amount about equal to the difference in length between paths 35 and 33. Engagement means 78 and 80 may comprise spherical balls or beads which are crimped about cord 54. The diameters of engagement means 78 and 80 are sufficiently small to pass through openings 74 in panels 72 and 70, but are also sufficiently large that they may not pass through a central aperture 77 of washer 76.

Cords 54 and 56 are only attached or attachable to the lead travellers 36a and 36b. Cords 54 and 56 pass around or through the other travellers 36 (at suitable openings provided therein) and are not attached or attachable thereto.

Lead travellers 36a and 36b are each connected to an adjacent traveller 36 (which in turn is connected to a train of subsequent slider blocks 36) by suitable link means 82. Link means 82 are movable relative to the travellers whereby when lead traveller 36a or 36b is moved a predetermined distance in the closing direction, such traveller 36a or 36b will commence pulling the subsequent traveller 36. When the lead traveller 36a or 36b is moved in an opening direction, the link means 82 is movable to allow the lead traveller 36a or 36b to approach and abut against an adjacent traveller 36. Thereafter further movement of lead traveller 36a or 36b will also cause travellers 36 to close up as well. Subsequent travellers 36 are either opened or closed in corresponding fashion by interconnecting link means 82 linking adjacent travellers 36.

In the illustrated embodiments, link means 82 comprises a stiff strip 84 having a shank 86 and a wide head 87. Each traveller 36 defines an aperture 88. Strip 84 of an

adjacent traveller 36 extends through aperture 88. The shank 86 is slidable within aperture 88. The head 87 may be inserted through aperture 88 from one direction, but cannot be removed therefrom in an opposite direction.

5 In operation, for ease of description it is assumed that the vertical blind apparatus 28 commences in the open position (as shown in Figure 3). In order to close the vertical blind apparatus 28, the human operator pulls
10 cord 54. Cord 54 in turn commences to pull cord 56 and lead traveller 36a toward the closed position. Cords 54 and 56 move in opposite directions. Dual pulley arrangement 58 allows cords 54 and 56 to move in opposite directions relative to each other around corner 20 without binding.

15 Cord 54 moves loosely through apertures 74 in lead traveller 36b, and at first the lead traveller 36b remains in the fully open position.

20 As lead traveller 36a reaches a predetermined spaced apart distance from a subsequent traveller 36, the connector means 82 between such travellers 36a and 36 commences to pull an adjacent traveller 36 toward the closed position.

25 As cord 54 continues to move through apertures 74 and 77, of lead traveller 36b, a point is reached where traveller engagement means 78 passes through the first opening 74 and contacts washer 76. Thereafter, washer 76 is pulled toward panel 72. Washer 76 then abuts against panel 72. At this position, lead travellers 36a and 36b both have the same distance to travel in order to reach the fully closed position.

30 As cord 54 is pulled further towards the closed position, both lead travellers 36a and 36b move toward the closed position. Both travellers 36a and 36b pull, by

by link means 82, a group or train of travellers 36 therebehind.

At the fully closed position, travellers 36 are spaced apart along the length of tracks 32 and 34 according to the lengths of the various link means 82. In order to close the slats 38, a rotation shaft 40 is rotated by the suitable rotation control means provided (but not shown in detail). For example, cord 41 may be pulled to rotate pulley 43 and to rotate shaft 40. As one shaft 40 rotates, the flexible coupling means 44 will also rotate therewith, causing the other shaft 40 to also rotate. In such fashion, the rotation of one shaft 40 is transmitted around corner 20. The rotation of shafts 40 causes the rotation of slat shafts 37 and slats 38 to the closed position through the suitable transmission means (not shown) provided in each traveller 36. The vertical blind apparatus 28 according to the invention is now in the fully closed position.

In order to open the blinds the rotation of shafts 40 is reversed.

Subsequently, when the slats 38 are in the open position, cord 56 is now pulled to open the vertical blind apparatus 28. The pulling of cord 56 causes engagement means 78 to be released from contact with washer 76. Furthermore, because cord 56 is tied to or integral with cord 54, lead traveller 36a commences to move toward the open position. As lead traveller 36a continues to move toward the open position, link means 82 between traveller 36a and an adjacent traveller 36 telescopes, or otherwise allows lead traveller 36a to move closer towards such adjacent traveller 36.

As cord 56 continues to be pulled through lead

traveller 36b, engagement means 78 passes outwardly through opening 74 in panel 70. Lead traveller 36b, however, remains in the fully closed position. Lead traveller 36a eventually will contact and push adjacent traveller 36, and thereafter will cause both travellers 36a and 36 to move toward the open position.

Eventually, engagement means 80 will pass through opening 74 in panel 72 in traveller 36b. Engagement means 80 will continue to be pulled until it contacts washer 76 and thereafter will move washer 76 toward panel 70, until washer 76 abuts against panel 70. At such position, lead traveller 36b will commence movement toward the open position. At such position, both lead travellers 36a and 36b will have to travel an equal distance to the fully open position.

As lead traveller 36b continues to move toward the open position, a connector means 82 between traveller 36b and an adjacent traveller 36 will collapse or otherwise allow traveller 36b to move closer to traveller 36. Eventually, traveller 36b will contact and push traveller 36, and thereafter, cord 56 will operate to pull both travellers 36b and 36 toward the open position.

In such fashion, all of travellers 36 close up against each other and the blind returns to the fully open position.

It will be appreciated that if the closing direction of track 34 were the same as that of track 32, engagement means 78 and 80 would be attached to cord 56. Furthermore, cord 56 would pass through openings 74 in panels 70 and 72 and through opening 77 in washer 76.

Similarly, the traveller engagement means 64, 78 and

80 will be attached to cords 54 and 56 depending on the specific desired vertical blind arrangement. By suitably positioning such engagement means 64, 78 and 80 and by providing suitable lead travellers, it is possible to design any vertical blind arrangement, such as normal opening, inverted opening, centre pull opening, inverted centre pull opening, multiple opening and double centre pull opening apparatuses as well as other designs.

In further embodiments, a vertical blind apparatus may include a multiplicity of corners and tracks of different lengths. In such an apparatus, cord 54 is fixed to a lead traveller having the longest path length. There may conceivably be more than one lead traveller having the same, but longest, path length. Cord 54 is also fixed to such other lead travellers, as well. Pairs of engagement means are attached to either cord 54 or 56, depending on the desired direction for opening and closing the vertical blind apparatus, on each side of the other lead travellers, having other shorter paths. The distance between the members of each pair of engagement means is equal to the difference in length between such other path and the longest path. The engagement means in each pair is specifically positioned, as described above.

In a further embodiment, if all lead traveller paths have the same length, the cords 54 and 56 are simply fixed to the lead travellers. They may, for example, be attached by means shown in Figure 4 or they may simply be tied to or wrapped around a portion of the lead traveller.

In a further embodiment, a lead traveller may have a design different from other travellers. The embodiment of Figures 3 to 5 illustrates lead travellers identical to other travellers. Such an arrangement is convenient for the manufacture of the blind apparatus. However, in certain

instances a lead traveller with special different characteristics may be desired.

5 Figure 6 illustrates one such alternate embodiment for a lead traveller 90. Lead traveller 90 defines only one panel 92 which allows cord 54 to pass therethrough at an opening 94. Engagement means 78 and 80 are unable to
10 pass through opening 94. Engagement means 78 and 80 are separated by a distance about equal to the difference in lengths of the longest traveller path and the path of lead traveller 90 plus the thickness of panel 92. Lead
15 traveller 90 may not include a slat shaft and may not have a slat affixed thereto. Furthermore, lead traveller 90 may not have a collapsible connection means connecting it to an adjacent traveller 36. Rather, lead traveller 90
15 may be rigidly fixed in close proximity to an adjacent traveller 36.

 According to a further embodiment the use of fixed connectors on beads 64, 78 and 80 may be dispensed with.

20 Instead, the cords may be gripped by clutch devices associated with the lead travellers in each group.

 These devices provide a form of sliding frictional grip on the cord so that the locations of the lead travellers can be self-adjusting.

25 One form of such a clutch device is shown in Figure 7.

 It will be seen to comprise a generally rectangular open sided frame 100, having a top 102, and sides 104, 106.

30 An edge strip 108 extends from the lower edge of wall 104. A resilient bendable flange 110 extends upwardly

from strip 108.

A pressure screw 112 is located in threaded hole 114 in wall 106.

5 Guide ribs 116-116 are formed on the inside of wall 104 to control cord 54 (or 56).

With the cord (54 or 56) between ribs 116, the screw 114 is operated to bend flange 110 towards wall 104.

10 This will squeeze the cord. By adjusting the screw pressure, a controlled degree of friction can be applied to the cord.

The clutch device can be formed as part of a lead traveller, or can be attached thereto by a bracket 118.

15 Other forms of clutch devices can be provided. For example, a clutch device could simply be an opening of a restricted size, in a traveller, or in a device such as a connector bead 64, 78 or 80, or even a washer 76.

All could be made to fit on the cord with a frictional sliding grip.

20 In operation in this embodiment, all lead travellers would start to move in unison. However those travellers in small groups would come to rest earlier than those in larger groups. The clutch devices would then allow the cords to slip so that the longest lead traveller could continue to move.

25 In a further embodiment, an additional horizontal track may be provided at the bottom of the vertical blind apparatus. Control cords may be provided to operate

travellers in both upper and lower tracks simultaneously.
By using opposed pairs of tracks to support the slats,
the blind apparatus may be supported in any position,
including a vertical position, a horizontal position or
any position therebetween.

5

The foregoing is a description of a preferred
embodiment of the invention which is given here by way
of example only. The invention is not to be taken as
described, but comprehends all such variations thereof
as come within the scope of the appended claims.

10

In a further embodiment the corners of the two adjacent
ends of the tracks can be joined at a corner by
an integral one piece junction member. The junction
member comprises two hollow insert portions adapted to
slide into the adjacent ends of track and two junction
wall panels extending from the junction member and meeting
at a hinge. The two insert members are hollow and contain
bearings for supporting the ends of the shaft. The wall
members are preferably joined by an integral plastics
self hinge.

15

20

In order to support the cords a pulley support wall may
also be formed integrally with the junction walls.
The pulley support wall is of reduced height and supports
two pulleys one for each cord.

19.

CLAIMS

1. A blind apparatus comprising:

at least two tracks having adjacent ends meeting
5 at a corner defined therebetween, the tracks defining two
opposite ends remote from such corner;

a rotation shaft longitudinally located relative to
each track;

10 support means affixed to each track for supporting
the rotation shaft;

at least one lead traveller slidably received within
each track, each lead traveller being constrained to move
along a lead traveller path of predetermined length within
its respective track from an open position at one end of
15 the path to a closed position at the other end of the
path;

a plurality of travellers, forming at least two groups,
a said group being associated with a respective said lead
traveller, the travellers being slidably received within
20 respective tracks, each traveller having a rotatable slot
shaft, each traveller being connected by suitable transmission
means to one of the rotation shafts whereby upon rotation
of the rotation shaft, the slot shaft may be rotated,
adjacent travellers in the same group being connected by a
25 connection means, each lead traveller being connected to
an adjacent traveller in its respective group by a further
connection means;

a flexible element engageable with said lead travellers and operable to move all said lead travellers simultaneously along said tracks between open and closed positions;

rotation control means attached to a rotation shaft,
and,

flexible coupling means connecting adjacent rotation shafts at the corner.

2. A blind apparatus as claimed in Claim 1 wherein the flexible coupling means comprises:

a helical spring;

collar means attached to each end of the spring, each collar means being affixed to a shaft.

3. A blind apparatus as claimed in Claim 2 wherein the said connection means comprise collapsible connector means.

4. A blind apparatus as claimed in Claim 3 wherein the longitudinal control means comprises pull cords connectable to the lead travellers, the pull cords being connected to each other at one end of the tracks.

5. A blind apparatus as claimed in Claim 4 wherein a dual pulley means is provided at the corner, whereby the pull cords may be supported.

6. A blind apparatus as claimed in Claim 5 wherein a pulley is provided at the said one end of the tracks to receive the pull cords.

7. A blind apparatus as claimed in Claim 6 wherein a first pull cord is attached by an attachment means to each lead traveller being constrained to move along a longest lead traveller path, and wherein pairs of lead traveller engagement means are attached to a pull cord adjacent each other lead traveller, the members of each pair of engagement

means being spaced apart by an amount about equal to the difference in lengths of the longest lead traveller path and the respective lead traveller path, and being positioned whereby, when the lead travellers are at the open position, one member of each pair of engagement means is adjacent its respective lead traveller on a side disposed toward the closed position.

8. A blind apparatus as claimed in Claim 7 wherein each lead traveller engagement means comprises a first bead affixed to a pull cord and wherein each lead traveller defines two parallel spaced apart panels defining first openings therethrough, the said pull cord extending through the first openings, the openings having sufficient width to admit the first beads therethrough, and a washer, having a central aperture through which the said pull cord extends, the washer being supported by the said pull cord between the panels, the central aperture having insufficient width to allow the first beads to pass therethrough.

9. A blind apparatus as claimed in Claim 8 wherein the attachment means comprises a second bead affixed to the first pull cord, the bead having a width greater than that of the openings in the panels.

10. A blind apparatus as claimed in Claim 8 wherein the attachment means comprises at least one loop of the first pull cord about a portion of the respective lead traveller.

11. A blind apparatus as claimed in Claim 1 wherein the flexible coupling means comprises a helical spring.

12. A blind apparatus as claimed in Claim 1 wherein the flexible coupling means comprises a flexible tube.

13. A blind apparatus as claimed in Claim 1 wherein the

flexible coupling means comprises a flexible cable.

14. A blind apparatus as claimed in Claim 1 wherein the flexible coupling means comprises a flexible shaft.

5 15. A blind apparatus as claimed in Claim 1 wherein a downwardly depending slat is attached to each slat shaft.

16. A blind apparatus as claimed in Claim 8 wherein a downwardly depending slat is attached to each slat shaft.

10

17. A blind apparatus as claimed in Claim 1 wherein substantially as hereinbefore described and as shown in figures 7 and 8 of the accompanying drawings.
